Digital Systems and Computer Organization

Contents

Unit 1 : Logic Gates and Boolean Algebra

Lesson 1 : Basic Logic Gates	1
Lesson 2 : Boolean Algebra	9
Lesson 3 : De-Morgan's Theorem	16
Lesson 4 : Simplification of Logic Circuits I	23
Lesson 5 : Simplification of Logic Circuits II	28

Unit 2 : Combinational Circuit

Lesson 1 : Half and Full Adder Circuit	41
Lesson 2 : Parallel Adder	47
Lesson 3 : Multiplexer	55
Lesson 4 : Demultiplexer	63
Lesson 5 : Decoder	67
Lesson 6 : 7-Segment Decoder	74
Lesson 7 : Encoders	77

Unit 3 : Sequential Circuit

Lesson 1 : Sequential Logic Circuit	81
Lesson 2 : SR (Set-Reset) Flip-Flop	87
Lesson 3 : J-K Flip Flop	91
Lesson 4 : D Flip Flop and T Flip Flop	94

Unit 4 : Sequential Machine

Lesson 1 : State Diagram and State Tables	99
Lesson 2 : Analysis of Asynchronous Sequential Circuits	105
Lesson 3 : Analysis of Synchronous Sequential Circuits	109
Lesson 4 : Design of Sequential Logic Circuit	113

Unit 5 : Counter and Register

Lesson 1 : Introduction to Counter	119
Lesson 2 : Synchronous Counter	123
Lesson 3 : Up-down Counter	127
Lesson 4 : Odd Sequence and Down Counters	129

Unit 6 : Memory Organization

Lesson 1 : Memory Terminology	133
Lesson 2 : Memory Operation	138
Lesson 3 : Read - Only Memory (ROM)	144
Lesson 4 : ROM Structure and Addressing	149
Lesson 5 : Random Access Memory (RAM)	152
Lesson 6 : Static and Dynamic RAM	155
Lesson 7 : Expanding Word Size and Capacity Expansion	159
Lesson 8 : Memory Mapping and Other Memory Devices	163

Unit 7 : A / D and D / A Converter

Lesson 1 : Interfacing with the Analog World	167
Lesson 2 : D / A Converter	175
Lesson 3 : A / D Converter	181

Unit 8 : Microprocessor Architecture	
Lesson 1 : Microprocessor Structure	187
Lesson 2 : Microprocessor Architecture	192
Lesson 3 : 8085 Microprocessor Architecture	200
Lesson 4 : Addressing Modes	204
Unit 9 : Fundamentals of Parallel Processing	
Lesson 1 : Types of Parallel Processing	209
Lesson 2 : Pipelined Vector Processors	213
Lesson 3 : Array Processor	216
Lesson 4 : Multiprocessor Systems	219
Answer to the MCQs	225

Preface

In the field of electronic devices, Digital Logic System plays an important role. The rapid development of various areas of digital technology makes it difficult even for a specialist to keep pace with this field. This book provides the reader with a foundation on digital logic systems and digital computer principles. The book emphasizes on operation, behavior and applications of microprocessor and microcomputers. These concepts include microcomputer architecture, memory structure, input/output facility and interfacing. In order to make the text self contained, materials on number systems, Boolean Algebra and required truth table are included.

Unit 1 describes all basic logic gates and Boolean theorems. Several examples are stated here. Combinational logic circuit simplification techniques are described in this unit. The techniques used are Boolean algebra and Karnaugh mapping. One can easily construct a logic circuit from the Boolean algebraic expressions.

Unit 2 explains the fundamental arithmetic operations such as different adder circuits, multiplexer, demultiplexer, decoder and encoder. The construction of LCD and their driving techniques are also illustrated. The practical application of a these combinational circuits are given in this unit.

Unit 3 describes the sequential logic family. The sequential circuits have wide applications in digital systems such as counters, registers, control logic, memories and other complex functions. All of these circuits operations are explained here with examples. The general operation of SR flip flop, J-K flip-flop, D-flop, T-flop are mentioned here which gives an easy understanding for the students.

Unit 4 discusses the functional interrelationship among input, output, the present state and next state etc. of the sequential machine. State diagram and state table are used to analyze the asynchronous and synchronous circuits. The diagram steps of sequential logic circuit are given at the end.

Unit 5 describes the counter and register used in microcomputer. In the digital electronics area one of the important field covers counters and registers. The operational characteristics of various asynchronous and asynchronous counters are explained in this unit. Design techniques of different types of counter with their state table makes it easier to understand the counting process.

Unit 6 describes the memory organization of microcomputer system. Memory terminology, different types of ROM, RAM and their architecture have been added in this unit. The techniques of expanding word size and capacity are illustrated in a lesson.

Unit 7 deals with analog to digital and digital to analog converter. Along with different terminology interfacing with the analog world has been described in this unit. Various D/A and A/D converter circuitry and their operations are described.

Unit 8 covers the design components of microprocessor. This unit analyzes the bus organization. The architecture of 8085 and the description of its registers are also given. Typical microprocessor addressing modes and instruction formats are also given.

Unit 9 discusses parallel processing. First part of the unit presents the classification of parallel processing. One of the important techniques called pipelining is also described here. Other important parallel processing techniques such as array processor and multiprocessor system are discussed.

At the end of each lesson of the unit there is an exercise. A learner can check his/her understanding of the lesson by answering the questions.
